## CALIBRE

## 1370

### 25.60 Q SCS CAL CORH CORM CORS 7 jewels Description et performances

The caliber 1370, destined for a man's electronic watch with analogical display, is fitted with a quartz vibrating 32768 times per second which ensures an accuracy of 5 seconds per month during wear, adjusted to this degree if necessary.

This watch, which indicates the hour, minute, second and the date, is still relatively slim in spite of all the functions it offers.

Correction of the minute and second is a very simple process thanks to an electronic hand-setting system controlled by a pusher located in the crown.

In drawn-out position, the crown enables correction of the hour (time zone) and date to be effected without disturbing the function of the watch.

The very simple and entirely modular conception of the movement ensures maximum servicing facility.

## 1. PRINCIPLE

The quartz resonator (1) is maintained at its selfsame frequency of 32768 Hz by an oscillator circuit (2). The frequency is adjusted by a trimmer (4) which enables corrections to be made within limits of $\pm 1$ second per day. Sometimes a fixed condenser (3) will be found, allowing the centering of the adjustment field.

The quartz oscillations are conveyed to the binary divider (5) which emits a signal at the frequency of 1 Hz . This signal is formed and amplified by a control stage (6) which sends
alternating polarity impulses to the motor coil (7). The magnetic field induced by these impulses causes the rotor to advance at the rate of one stop per second.

The motion of the motor is transmitted to the wheel-train (8) and display (9) through the medium of a pinion fitted on the rotor axle (10).

The battery (11) supplies the necessary energy to the integrated circuit which feeds both quartz and motor.

The push-button (12) located in the center of the crown controls a logical circuit (13) which conveys to the motor the necessary data for correction of the second (gain or loss). This same push-button also enables the motor to be set at fast rate for correction of the minute hand.

The crown (14) has a resting position without function. In drawn-out position, it allows correction of the hour hand and the date to be effected.

## 2. DESCRIPTION OF MOVEMENT

The movement is composed of three modules:
a) The electronic module with its quartz forms the time basis.
b) The motor module which converts electric time data into rotating mechanical motion.
c) The display module grouping together the indicating and correcting systems.

## a) Electronic module

## The electronic components:

quartz Q
possible fixed condenser C
trimmer T
monolithic integrated circuit CI
are fixed on a printed circuit and together form the electronic module.

Connection with the motor is ensured by 2 contact bridles.

The battery feeds the module through the negative contact spring, return of the current being obtained through the gilt screws. The integrated circuit groups together approximately 400 transistors on a surface of $5 \mathrm{~mm}^{2}$. It fulfils several functions which figure in the following block-plan (Fig. 1):

The oscillator circuit CO maintains vibration of the quartz at 32768 Hz .

The frequency dividing circuit CD , formed by 15 binary levers (divider by 2), converts the oscillator signal into impulses of 1 Hz . A connection on the 10th dividing stage enables the required frequency of 32 Hz to be used for time-setting purposes.

The control stage CM feeds the motor (M) with alternating impulses of suitable amplitude and duration.

The rate selector CS is controlled by the crown pusher PC. This single pusher enables the following 3 functions to be carried out:
a) A brief push produces an additional impulse between 2 normal impulses, and the watch advances one second.
b) A prolonged push stops the impulse train. The motor remains at a stop as long as the pusher is pressed.
c) To switch the motor onto the fast rate at 32 Hz , the following operations must be carried out:
press the pusher for 5 seconds, release briefly, press again. The motor turns at fast rate as long as the said pressure is maintained, and then resumes its normal rate.

## b) Motor module

This motor is of the electromagnetic, rotating, step-by-step type. When working normally, it receives a driving impulse every second.

However, when time correction takes place, the motor receives 32 impulses per second.

## It consists chiefly of the following units:

magnetic circuit (1), (2), (3)
rotor (4)
pinion (5)
coil (6)
bridge (7)
printed circuit (6)

## The motor functions in the following manner:

When a current goes through the coil (6), a difference in magnetic potential is set up between the parts (1) and (2) of the magnetic circuit, creating a magnetic field around the airgaps (9). This field in its turn exerts forces on the rotor teeth (4), the result of which is a torsion couple.

Connection of the motor is ensured by the printed circuit (8) against which rest 2 bladesprings belonging to the electronic module.

## c) Display module

## This module comprises:

## on the movement side:

the battery
the wheels: intermediate, second, third, center, as well as the minute wheel
the mechanism

## on the dial side:

the remainder of the reducing wheel-train with the setting wheel
the date

## Wheel-train

The motor pinion (1) drives, through the intermediate wheel (2): the second wheel (3), the third wheel (4), the center wheel (5), the double minute wheel (6 and 7), and the hour wheel (8). Fig. 2

## Date

The hour wheel drives the setting wheel (9) which on the one hand meshes with the clutch wheel (10) and, on the other hand - by means of a finger - with the date indicator driving wheel (11). A pinion forming part of the date indicator driving wheel drives the date indicator (12). Fig. 2

## Time corrector

The minute wheel consists of 2 superposed units ( 6 and 7), magnetically coupled by means of the magnetized washers. When the handsetting stem is in resting position, the wheel operates as one single unit. In drawn-out position of the stem, the hour wheel (8) as well as the minute wheel plate (7), are driven by the clutch wheel (10) and setting wheel (9) without losing the exact indication of second and minute, the magnetic couple of the minute wheel being weaker than the couple conveyed by the motor.

## 3. FUNCTIONING OF THE CORRECTING DEVICES

## Stem in position 1

no function

## Continued pressing of pusher

the second stops

Press pusher for 5 seconds
release briefly
press again
rapid advancement of the minute hand (1 dial revolution in 2 minutes); after this operation correct position of the hour hand if necessary.

## TECHNICAL DATA AND PERFORMANCE OF CALIBER 1370

| Dimensions | Diameter 25,60 mm |
| :---: | :---: |
|  | Height 4,80 mm |
| Frequency of resonator | $32768 \mathrm{~Hz}=2^{15}$ |
| Quality factor | Typical 100'000 |
| Thermic coefficient | $0.1 \mathrm{~s} / \mathrm{d}$ for a variation of $\pm 5 \mathrm{C}$ |
| Consumption | typical $3.4 \mu \mathrm{~A}$ maxi $4.0 \mu \mathrm{~A}$ |
| Running time with 67 mAh battery | guaranteed 12 months typical 24 months (SSIH battery No. 9917) |
| Variation during wear | better than $\pm 5$ seconds par month |
| Resistance to shocks | shocks conforming to NIHS norms : residual affect recoverable through adjustment system |
| Resistance to magnetic fields | NIHS magnetism test : no affect |
| Temperature functioning limits | from 0 to $+60^{\circ} \mathrm{C}$ |

## 11.0 adjustment of the rate

11.1 Open the case, place watch without back on the captor (movement side up) and press key $" \leq 15 \mathrm{~Hz}$ " of Deltatest ( 1 Hz for ODT 1)
11.2 Adjust watch by means of trimmer, avoiding any possible pressure during this operation. Correct the rate according to the client's indications, or to $+0,20 \mathrm{~s} / \mathrm{d}$. (back open).
11.3 Close the case, and check that the rate is at $+0,20 \mathrm{~s} / \mathrm{d}$. (the effect of the back is negligible, thanks to the protection of the electronic module)
11.4 Water-resistant models : check water-resistance.
DIAGNOSTICS
